Introduction

Purpose of the program is to solve electrostatic systems for which analytical solution does not exist.

Accuracy is compared against a system for which analytical solution does exist (System A).

Computational performance compared against various parameters...

Iterations

Computing system A and comparing the results with different number of iterations to the analytical solution:

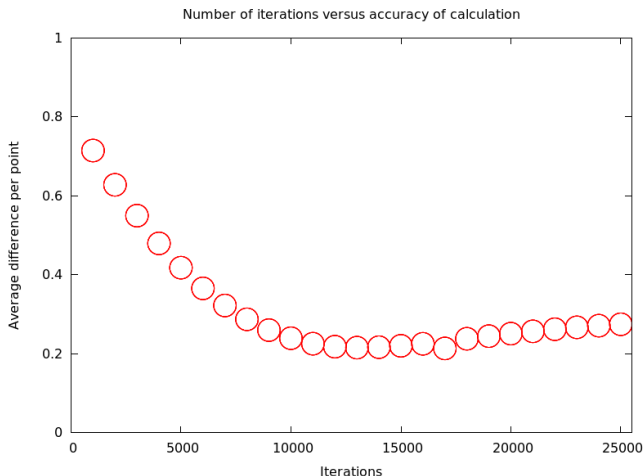

Figure : Relaxation parameter = 1, desired convergence = $1e-20$.

Iterations continued

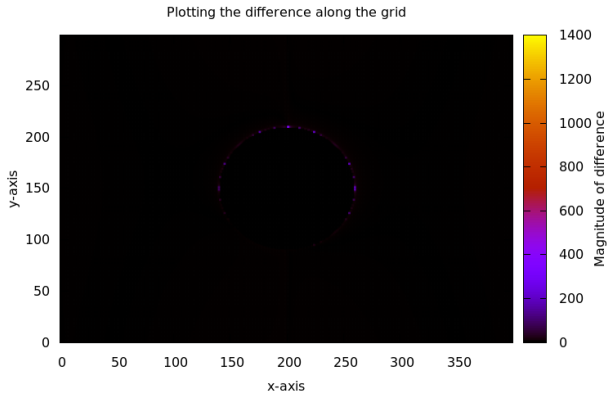

Figure : Computation done with 12000 iterations

Relaxation parameter

Running the *eStatics* package with a varying relaxation parameter to a desired convergence shows that there is an optimal value, which is dependent on the electrostatic system.

Relaxation parameter continued

Computing system A to $1 * 10^{-4}$ convergence with different relaxation parameters to determine optimal value:

Relaxation parameter continued

Optimal value of about 1.975 for System A.

Relaxation parameter continued

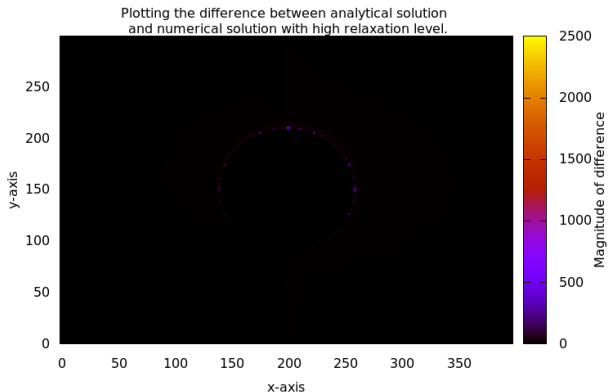

Figure : Figure showing difference between analytical solution and numerical solution with relaxation parameter of 1.975 and 428 iterations

Convergence

Running the *eStatics* package with a varying number of iterations and a varying level of desired convergence shows that the required iterations vs desired convergence is roughly inversely exponential.

Convergence continued

Computing system A to a desired convergence and comparing with time taken:

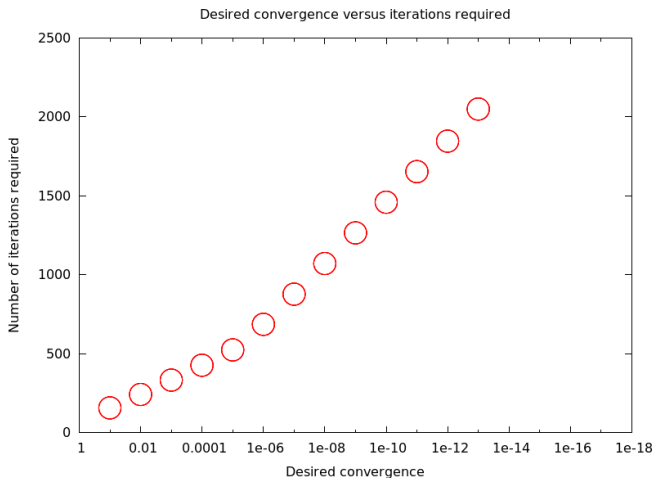

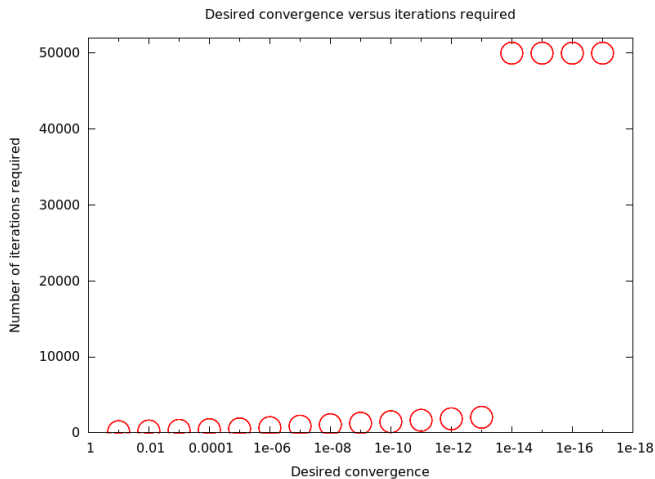

Figure : Relaxation parameter = 1

Convergence continued

The rest of the data points are off the scale:

Multithreading

Multithreading has an effect on the computational speed, but not on the number of iterations.

Allows a higher number of iterations to be run in the same time, possibly allowing larger input images to be used while keeping the length of the computation reasonable.

Multithreading continued

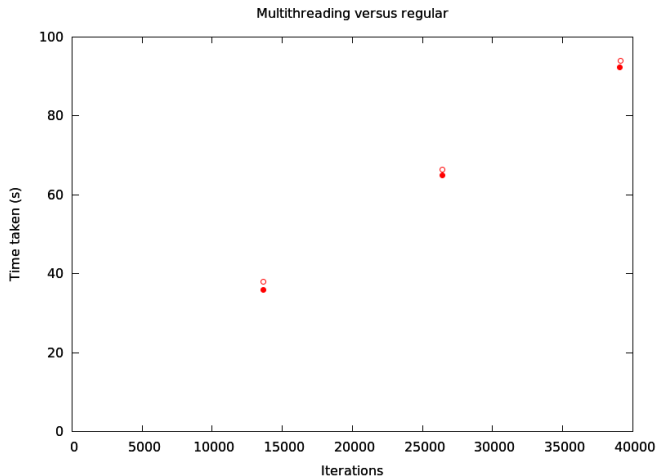

Figure : Filled circles = multithreaded, open circles = single thread.
Computation done on a 400×300 grid.

Multithreading continued

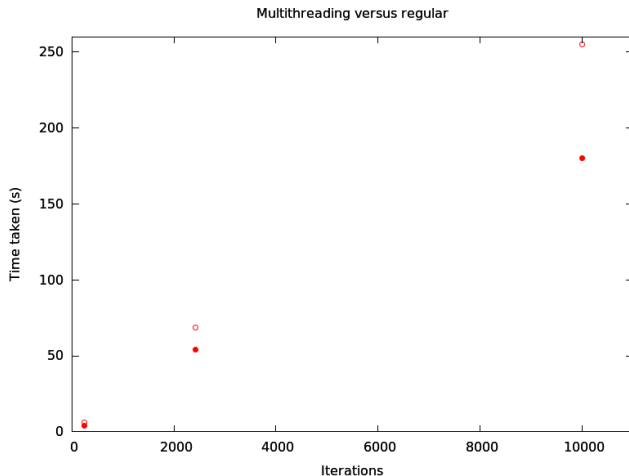

Figure : Filled circles = multithreaded, open circles = single thread.
Computation done on a $1280 * 720$ grid.

Further work

The *eStatics* package could be generalized to apply to a wider range of applications:

- ▶ Temperature distributions
- ▶ Gravitational fields
- ▶ Anisotropic blurring (image processing)

Basically anything that the Laplace equation applies to. Could also be increased to three dimensions to solve more complicated electrostatic problems.
